

EVALUATION OF OPERATIONAL HYDROLOGICAL ENSEMBLE FORECASTS IN SWEDEN

by

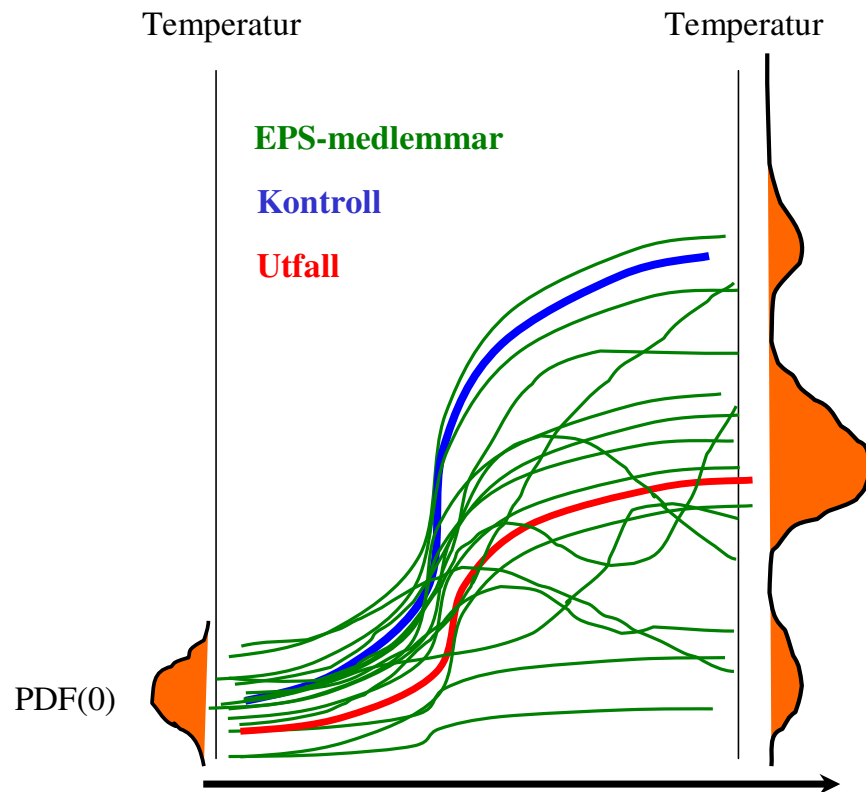

Göran Lindström, Anna Johnell and Jonas Olsson,
Swedish Meteorological and Hydrological Institute (SMHI)
Hydrological Forecasting Section and Research Department
Norrköping, Sweden

CONTENTS

- **Overview** of the hydrological ensemble prediction system (EPS) at SMHI
- **Evaluation** of 30 months of data from 45 catchments in Sweden

METEOROLOGICAL EPS FORECASTS

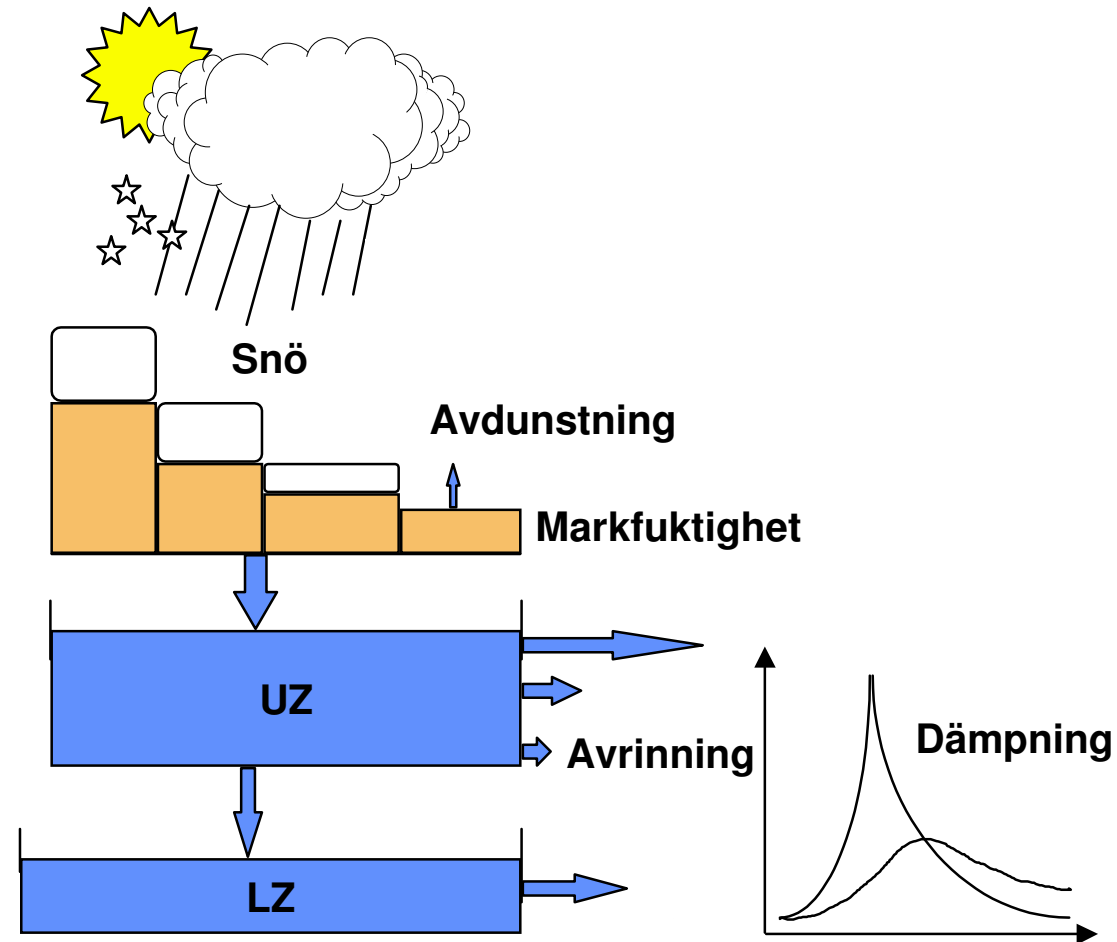

- Control forecast + 50 EPS members

EPS Meteorogram
Kultsjon 64.9° N 15.0° E
Deterministic Forecasts and EPS Distribution 15 May 2003 12 UTC

CHR 30-31 March 2006

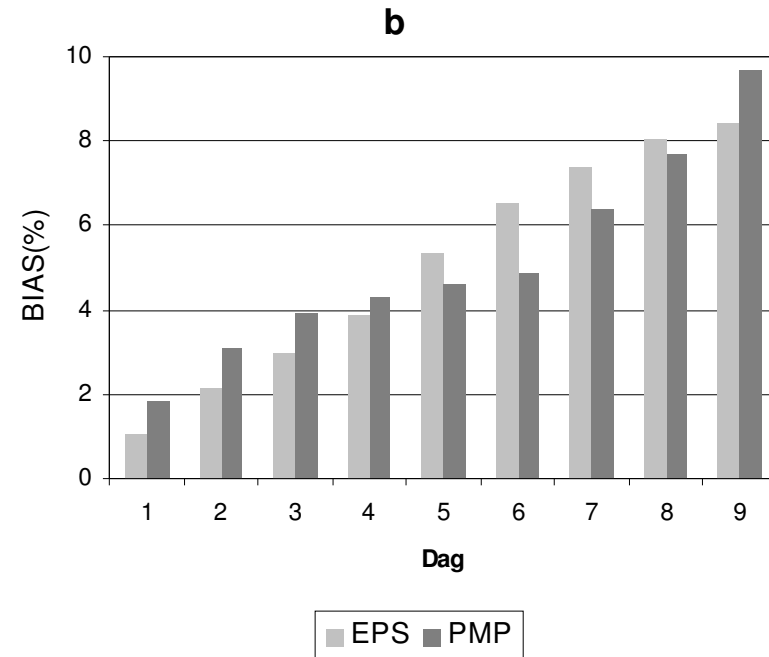

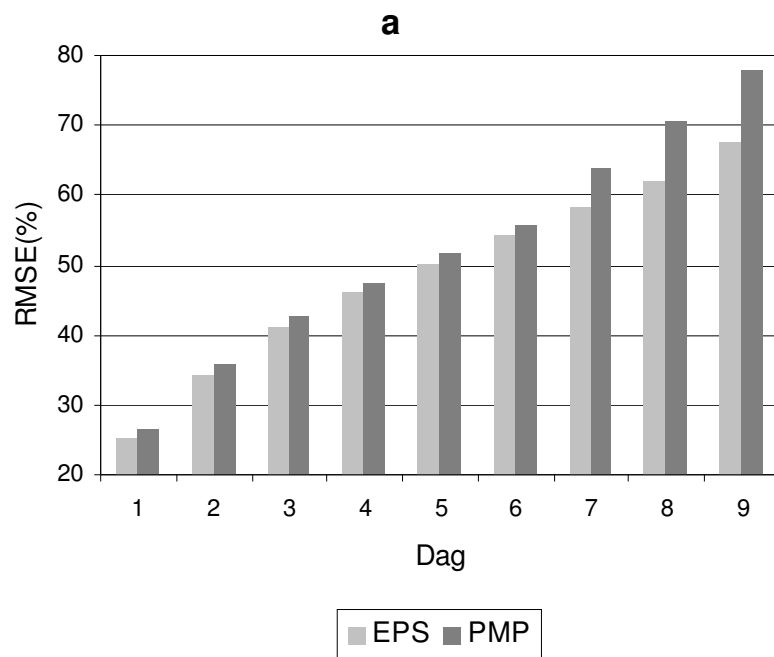

DETERMINISTIC EVALUATION

- EPS median vs. existing operational deterministic forecast (PMP)

DETERMINISTIC EVALUATION

- EPS median vs. existing operational deterministic forecast (PMP)
- Figures below are averages over all catchments

PROBABALISTIC EVALUATION Methods

- **Percentile-based:** how often does the observation fall between different EPS percentiles?
- **Threshold-based:** how well do estimated and observed probabilities of exceeding critical discharge levels agree?
- **Qualitative spread-skill:** how does the relation between EPS spread and forecast error look?

PROBABALISTIC EVALUATION

Qualitative Spread-skill: results OBS

- **Spread:** distance between EPS quartiles 25% and 75%
- **Skill:** relative mean absolute error, with error = EPS median – observation

PROBABALISTIC EVALUATION

Reference discharge (Q)

- **Problem:** two sources of uncertainty exist – in the **meteorological forecast** and in the **hydrological model** – and need to be separated
- **Reference 1:** observed Q (**OBS**) – error includes both sources of uncertainty
- **Reference 2:** simulated Q using a perfect meteorological forecast (**HBV**) – error includes only uncertainty in the meteorological forecast

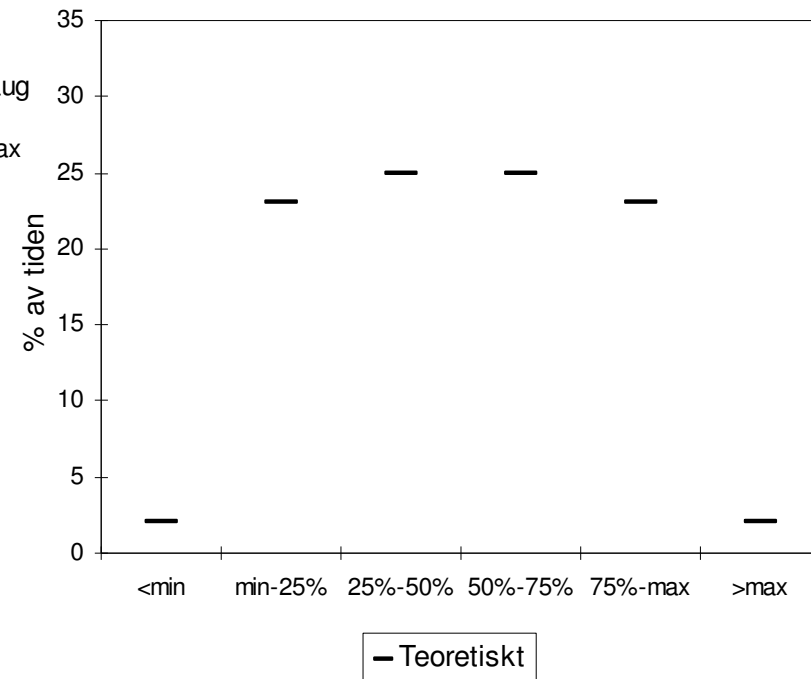

PROBABALISTIC EVALUATION

Percentile-based: methodology

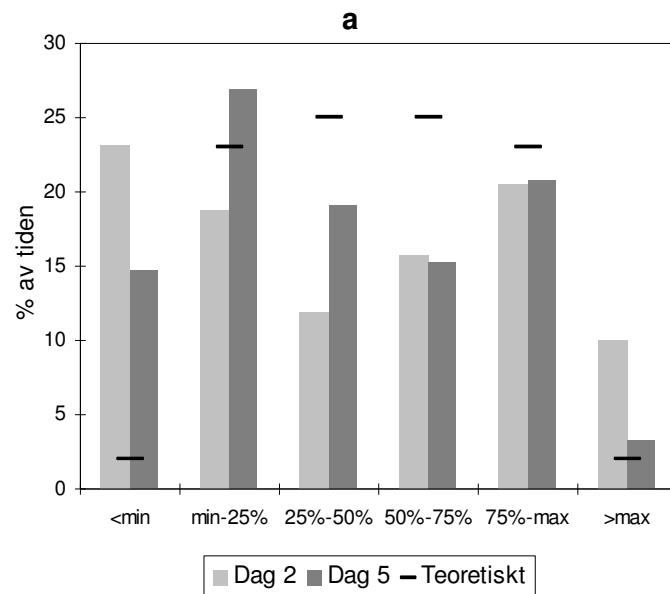

histogram of observations
if EPS spread is accurate

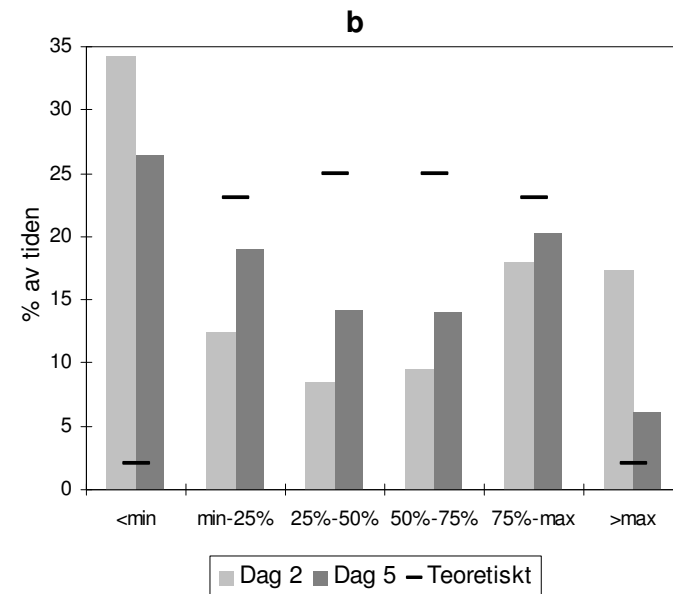

PROBABALISTIC EVALUATION

Percentile-based: results HBV

Best catchment (Hammarby)

All catchments

- Occasions when observation < EPS min generally (75%) associated with decreasing discharge

PROBABALISTIC EVALUATION

Percentile-based: results OBS

Best catchment (Pepparforsen)

All catchments

- Difference in agreement with theoretical pattern suggests met. forecast error \approx hyd. model error

PROBABALISTIC EVALUATION

Threshold-based: methodology

- **Discharge threshold levels:** 'high' (exceeded 30% of the evaluation period) and 'very high' (10%)
- **Included:** only cases when discharge below threshold at the time of forecast
- **Evaluation:** comparison of estimated exceedance probabilities and corresponding observed frequency in categorical terms (false alarms, total misses) and as reliability diagrams

PROBABALISTIC EVALUATION

Threshold-based: categorical - results

- **False alarm (FA):** EPS min above threshold (i.e. all members) but in reality not exceedance
- **Total miss (TM):** EPS max below threshold (i.e. all members) but in reality exceedance

| | | Dag 2 | | Dag 5 | |
|-------------------|-----|--------|--------|--------|--------|
| | | FA (%) | TM (%) | FA (%) | TM (%) |
| Högt flöde | HBV | 22.5 | 0.5 | 25.9 | 0.6 |
| | OBS | 60.4 | 1.4 | 54.4 | 1.4 |
| Mycket högt flöde | HBV | 20.7 | 0.2 | 19.7 | 0.3 |
| | OBS | 50.4 | 0.5 | 40.5 | 0.5 |

PROBABALISTIC EVALUATION

Threshold-based: reliability - methodology

- **Reliability diagram:** plot forecasted exceedance probabilities vs. corresponding observed frequencies

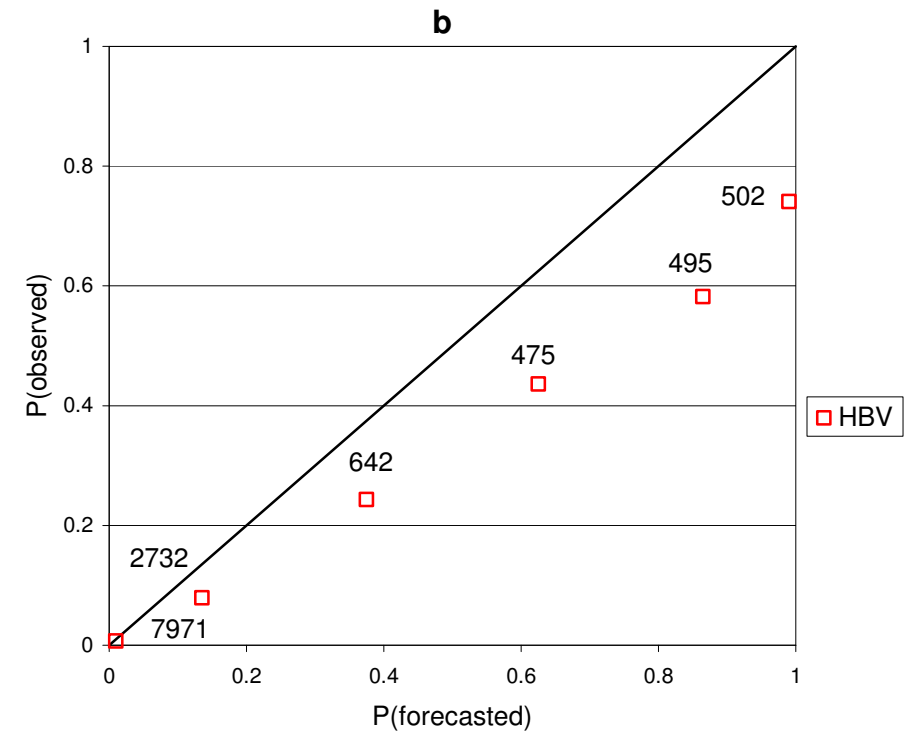

PROBABALISTIC EVALUATION

Threshold-based: reliability – results HBV

Threshold 'high', all catchments

Day 2

Day 5

PROBABALISTIC EVALUATION

Threshold-based: reliability – results HBV

How good?

Comparison with ECMWF precipitation

How to improve?

Calibration (multiply by 0.7)

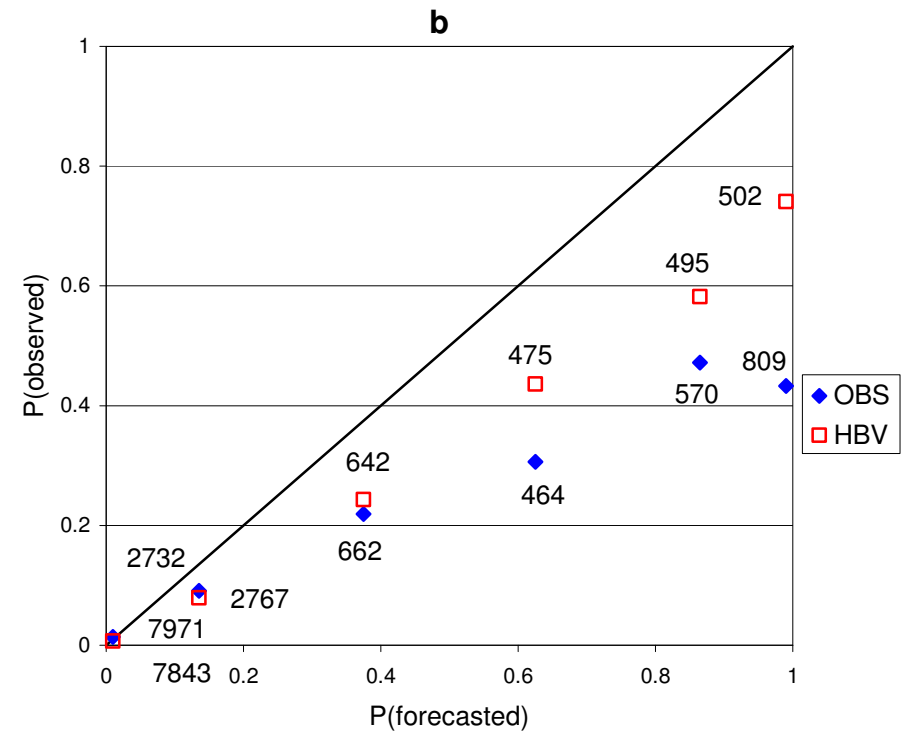

PROBABALISTIC EVALUATION

Threshold-based: reliability – results OBS

Threshold 'high', all catchments

Day 2

Day 5

INTERPRETATION AND PRESENTATION

Hydrological model uncertainty

CONTINUED WORK

- 'Interpretation and presentation of EPS forecasts'
- 1. Incorporation of hydrological model uncertainty
- 2. Most suitable way of presenting the results

CONCLUSIONS

- **General: hydrological ensemble forecasts provide an added value compared with traditional, deterministic forecasts**
- **Deterministic: EPS median equal to or slightly better than traditional PMP forecast**
- **Deterministic: EPS bias positive**
- **Probabalistic: EPS spread needs to include hydrological model uncertainty for representing the observed discharge**
- **Probabalistic: qualitative use of EPS by e.g. 'forecast uncertainty classes' is possible**
